ABSTRACT
This article compares mining and post-mining landscapes on old maps and in modern aviation photography of three regions around the towns of Jáchlomov, Most and Kladno in Czechia. The three regions differ not only in the type of mining, but also in their historical development and current management. The goal of the article is to compare these regions and evaluate the changes and consequences of mining on the landscape in different time periods using cartographic sources. Another aim is to identify specific landscape elements related to mining by drawing on old maps and state map series of the three regions.

Human socio-economic activities have shaped different types of cultural landscapes for centuries. Agricultural, industrial, transportation and other activities change the landscape and leave their imprints even years or centuries after they are over (Taylor 2003). Different types of cultural landscapes reflect specific human activities (or their combination) and they can also remind us of the past that is imprinted in them.

When researching mining landscapes, it is important to analyze values and meaning of areas as well as its development and changes. Historical geography and historical cartography provide tools for such research that enable us to understand the processes in the past and use them to explain and understand the current state of these landscapes.

Thanks to historical geographical analysis, it is possible to compare and research development of areas. Such knowledge is important for realizing values and meanings of an area, maintaining landscape heritage and responsible management. It also allows for the relicts of mining activities to be perceived as part of cultural landscapes and to be perceived as areas of interest: restaurants, concert halls, theatres, conference venues, etc.

Zollverein was inscribed into the UNESCO list of World Heritage Sites in 2001.
a combination of time and space organisation of processes, one of the main tasks of historical geography and cartography (Schenk 2011; Jelen 2018).

3. Cartographic sources as a source of information about mining landscapes

Historical geography uses a diverse range of historical geographical sources that include not only historical sources, but also sources from related technical disciplines and natural sciences (Semotanová 2006). The sources of information about the past can be categorized in multiple ways. Most commonly, the categories are the following: tangible sources, written sources, and images/iconographic sources that include a distinct group of cartographic sources. These are old maps that provide valuable information about the shape of landscapes in the past and that help us to trace anthropogenic landscape changes. They can provide visual information about landscapes and specific buildings as well as processes in the past and about the ways they were captured in maps (Tůmová 2018; Win 2014). The most useful and the most used categories of cartographic sources are so called comparative sources (e.g. Müller’s survey, military surveys, Stable Cadastre or old aerial photographs and orthophotography) and individual sources (e.g. Klaudyán’s map of Bohemia, Aretin’s map of Bohemia, Vogt’s map of Bohemia). This division is related to the evolution of map production as individuals were the first ones to initiate creating maps, followed only later by state institutions (Tůmová 2018).

3.1 The oldest maps of Bohemia – individual maps

The first maps with simple thematic map elements, mostly related to economic activities, but also to cultural ones, appeared in the Czech lands already at the beginning of map production in the 16th and 17th century. These old maps, together with written and iconographic materials, allow a complex study of scarcely studied pre-industrial landscapes. They can also contribute to improve the knowledge and reconstruction of the past landscapes and also to evaluate long-term changes of landscapes. They also provide material for discussion on relationships, approaches and landscape protection and protection of landscape heritage in the present and the future (Marcucci 2000; Antrop 2005).

In the early modern period (from the 16th to the 18th century), there were mostly individual maps made. Cartographic research on semiotic and cartometric analyses of selected old maps uses mostly individual maps of early modern period (Bayer 2009; Potučková 2012; Semotanová 2001). The oldest maps of Bohemia, e.g. Klaudyán’s map, Aretin’s map, Vogt’s map, do not, however, provide much detailed and accurate information about landscape (Mucha 1992; Kuchař 1959). But many of them already include cartographic symbols to provide information about locations of raw materials and about mining activities.

The first testimony of mining activities and sources of raw material in Bohemia is found in the third oldest individual map of Bohemia that was published in 1619. Its original title was Regni Bohemiae Nova et Exacta Descriptio, i.e. New and Accurate Description of the Bohemian Kingdom. Its author was Pavel Aretin from Ehrenfeld and the scale was set by Karel Kuchař to be 1 : 504,000.

The Pavel Aretin included names of 1,200 settlements, mostly in Czech, but also in German. The elevation is depicted by hill profiles. The map legend (figure 1) contains 16 symbols for free royal towns, royal towns, serfdom town (2 symbols), villages, castles, forts, monasteries, towns with castles, villages with castles, deposits of gold, silver, tin and iron ore, spa and glass production (Kuchař 1936).

In the 18th century, the cartographers started to use new symbols also for important economic, natural and cultural processes. The example is the map by Johann Gregor Vogt published in 1712. The map’s

The map of the Bohemian Kingdom (Mappa Geographica Regni Bohemiae) published in 1720 by Jan Kryštof Müller is considered one of the most important cartographic works of Czech history. The map is divided into 25 sheets and its dimensions are 282.2 × 240.3 cm. The scale is around 1 : 132,000 (Kuchař 1959). The map was ordered by the state (the Austrian Empire) to map military, administrative and economic features. That is why there is not only detailed topographic information (settlements, water, elevation, vegetation, roads), but also farms, abandoned settlements, mills, vineyards, mines of gold, silver, tin, copper and iron, brass casting, hammer mills, iron smelters, glass production, post offices and others. As the approved symbols were not enough for Müller, he added written information in the maps or used different symbols than those in the map legend. According to Kuchař (1959), the map includes the total of 12,495 places with names and the map legend describes (in Latin and in German) 48 well selected symbols (figure 3).

The explanations in the map prove the importance of raw materials for the economy at the time. The most important were the deposits of gold, silver, iron ore, copper, alum, sulphates and related places of metalworking (Semotanová 2011). Müller’s map is more detailed compared to the ones by Aretin and Vogt, also thanks to its scale. The map legend maintains the symbol of two crossed hammers as the symbol of mining.

3.2 State map series from the second half of the 18th century

State map series cover larger areas, usually whole countries, using the same map projection, scale and usually also the same legend. Among these series,
we can already find the first maps by Jan Kryštof Müller; then military surveys, Stable Cadastre, sets of aerial photography, newer maps of larger areas (for instance regions) and of course the newest state map series. Such series, called comparative cartographic sources, allow wider comparative research (Tůmová 2018). Important comparative sources on the territory of Bohemia are the map series created and used between the mid-18th century and the beginning of the 20th century. These sources are so called military surveys whose scale is suitable for landscape studies. Combined with Stable Cadastre sources, they are a wonderful starting point for the study of landscape changes in the modern period. On these maps, we can observe buildings and building complexes that have undergone many changes or have disappeared, partially or completely (Hauserová 2015).

3.2.1 Military surveys
The three military surveys were the first attempt to capture the whole area of the Habsburg Monarchy. They were done because of an urgent need to have a unified map system for military purposes. The first military survey was done between the 1760s and 1780s with the scale 1 : 28,800. It captures the baroque landscape at the end of the early modern period still with some remainders of the feudal relations.

The second military survey was done between 1806 and 1869 in the territory of Austria-Hungary. The scale was the same, i.e. 1 : 28,800. The mapping was based on an accurate trigonometric net and it was based also on the map documentation of the Stable Cadastre (see below). Due to the time period that elapsed from the first survey, the object of the mapping was the landscape of the Czech lands in the time of the Industrial Revolution. The content of the survey is basically the same as of the first one. It contains roads, brick buildings, and stone bridges. The natural elements included are fields, meadows, woods, ponds and watercourses. The elevation is indicated by Lehmann’s slope hachures.

The third military survey of Austria-Hungary was done between 1869 and 1885 when the number of new railways, roads, ore and coal mines, industrial projects and plans to make some of the rivers navigable required precise topographic information (Hauserová 2015). The new survey had the scale of 1 : 25,000. Compared to the second survey, the elevation is recorded in a better way – not only by hachures, but also by contour lines and spot heights. The result of the survey are coloured so called topographic sections that were reprinted in special maps (1 : 75,000) and general maps (1 : 200,000). The survey was once again based on the Stable Cadastre.

The third survey managed to capture the period of intensive industrialization of the Czech lands – this is visible mainly at the edges of cities and town. The landscape on the map is full of different types of roads. Mining and processing of raw materials is increasingly intensive. The map legend is very detailed and as such it provides deep insight into types of soils, vegetation, structure of settlements and sometimes even into functions of different buildings. The agricultural land, on the other hand, did not change significantly compared to the second survey (Hauserová 2015; Semotanová 2006).

3.2.2 Stable Cadastre
Information about all the land in the Austrian Empire was included in the Stable Cadastre whose scope was to provide exact documentation for land taxation. The mapping of Bohemia took place from 1826 to 1830 and again from 1837 to 1843. The scale was 1 : 2,880.

Fig. 4 Part of the map legend of the Stable Cadastre with symbols for surface mines. First row: deciduous forests (by growth), mixed forests, thickets, draws; second row: sand pits and gravel pits, clay pits, quarries, barren soil, fallow land.
Source: The Map Collection of the Faculty of Science, Charles University
One cadastral map was made for each municipality and its land lots, including all the borderlines. Due to the need to express the value of each lot, the land cover and land use were documented very precisely and in much detail. The cadastral maps capture the Czech lands in the time of intensification of agriculture and beginning of the Industrial Revolution. Due to the scope of the cadastre (taxation), there is no information about elevation. The maps were made with a single map legend and the same colours (figure 4). For example brownish grey is used for woods, bright green for parks, gardens and meadows, ochre for fields, light green for pastures (with letters G or GW which signal municipal pastures). Carmine is used for brick buildings, stone bridges, weirs and roads, dark carmine for public buildings, yellow for wooden buildings and bridges. White is used courtyards and squares and brown is used for roads, blue for water (Plánka 2014). As for the surface mines, the maps include clay pits, stone, sand and gravel quarries that are indicated by symbols (figure 4).

3.2.3 Aerial photographs
It is possible to compare the information from old maps with newer or modern maps. From the documentation that is easily, it is necessary to point out the importance of orthophotographs of the surface of Czechia that have been taken from 1936 onwards (with only a break during the Second World War) for military purposes. The photographs are archived in the Military Geographical and Hydrometeorological Institute in Dobruška (VGHMÚř in Dobruška 2020).

The next military survey was done in the 1950s. The result was the first Czechoslovak map series of the whole country done by aerial photogrammetry. It is a unique representation of the country before the post-1948 societal changes could be reflected in the landscape. The collectivization of agriculture was still not much visible in the photographs and the towns were captured before the construction of flat complexes. The photographs capture in detail mountain landscapes and it is possible to identify mines, mining operations and other elements.

3.2.4 Contemporary orthophotography of Czechia
Orthophotography of the Czech Republic is a periodically updated set of coloured orthophotographs in the same format of the state map, i.e. 1 : 5,000 (2 × 2.5 km). The photographs are coloured and georeferenced representation of the Earth’s surface. Each zone reflects the territory in the same year. Since 2016, the orthophotographs have been made in pixel 0.2 m. Moreover, the photographs have been taken with a digital camera since 2010 and as a result, the quality of photographs has been much higher (Geoportal ČUZK 2020). Since 2003, the orthophotographs have been provided by the State Administration of Land Surveying and Cadastre and the Military Geographical and Hydrometeorological Institute. As of 2012, the photographs of Czechia and the preparation of the orthophotographs are done every two years. Each year, half of the territory is photographed.

4. Analysis of the sample territories
Three locations in Czechia were chosen for the comparative study. They have all been changed by intensive mining. Each of them represents a different raw material, historical period and method of mining. Thanks to that, it is possible to compare the way mining was reflected in different map series and what landscapes changes have occurred in relation to mining. For the comparison, the Stable Cadastre, the third military survey, aerial photographs from the 1950s and current orthophotography were used.

4.1 The region of Jáchymov
The first region is the region of Jáchymov in the Ore Mountains. It is an area with the oldest mining history in Czechia. The first evidence of mining dates back to 1300 (Hloušek 2017). At the beginning of the 16th century, the mining of silver ores expanded and Jáchymov became the second biggest town in the Bohemian Kingdom after Prague as it had almost 25,000 inhabitants. During the same century, many new mines were founded and the centre of the miners’ town was built. There was also a new royal mint built to produce silver coins – thalers. The mining is documented already in the oldest maps. In the Are- tín map we can see two simple symbols: crossed hammers for a mine and a moon for the material, i.e. silver (see figure 5). Müller’s survey uses only the symbol for silver (moon), but it is used five times in the region (see figure 7) to emphasize the extent of mining in the area. Also in Vogt’s map of Bohemia, the...
mining in Jáchymov is documented by two symbols: crossed hammers for a mine and a moon for silver (see figure 6).

When the deposits of silver were used, the mining in the region continued from the 17th to the 19th century with cobalt, bismuth, nickel, tin, and later also uranium. Since the mid-19th century, radioactive materials were mined. Firstly, to be used in uranium colours, later for extraction of radium and in the mid-20th century the uranium was extracted for military purposes. The last period of mining between 1945 and 1964 changed the landscape the most as it was very intensive mining of uranium ores to be used in the former USSR. After 1945, more than 25 mines were opened in the region, more than 1,000 kilometres of shafts and 8,000 tons of uranium were excavated (Jelen, Kučera 2017). The landscape was changed the most by huge soil tips, but also by new buildings intended for separation and elaboration of ores. In relation to the uranium extraction, there were large numbers of miners working in the Jáchymov region. Some of them were prisoners convicted for both political and non-political crimes. The prisoners lived in labour camps – there were dozens of them around Jáchymov (Hloušek 2017).

After the uranium deposits were gone, the communist government wanted to delete all the traces of mining that remained in the landscape. The mines were destroyed; labour camps were razed to the ground. The uranium mines were supposed to be forgotten. This is documented also by construction of new cottages and recreation areas in the place where the mines and labour camps had been (Hloušek 2017). The situation changed in 1989 and the remaining traces of the mining started to be used to remember the local heritage. The idea is to protect the landscape that witnessed more than 800 years of mining and keep it as a complex. The highlight of these attempts was the inscription of the landscape of Krušnohoří/Erzgebirge in the UNESCO World Heritage List in 2019 (Karel, Kratochvílová 2013; Jelen, Chromý 2018, UNESCO 2020).

When comparing the cartographic sources, it is possible to see that the landscape right around the historical centre of Jáchymov is labelled as a place of silver mining in the Stable Cadastre (figure 8). The soil tips on the hillside of Kailberg, to the west from the church, are partly covered with grass. There are pastures (W – Weiden) and rubble (E – Egärten). However, some hillsides are still bare and rocky – and not fertile (ö – Öde). The large soil tip with the soil from the closest mine Svornost is also marked as not fertile (1). In contrast to the current situation, there are no woods on the hills above the town because wood was commonly used in the mine constructions. On the platform above the square, a horse mill was still maintained in the time of mapping (2). The horse mill provided vertical communication in the silver mine of the Emperor Joseph II. The map of the third military survey documents the mining with the symbol of crossed hammers (figure 9). The soil tips are indicated by contour lines and hachures, but they are not labelled, therefore it is almost impossible to identify them without previous knowledge of the area. The uranium extraction is then visible in the orthophotograph from 1953 (figure 10). In the photograph, there is also visible the labour camp Svornost (next to the mine Svornost). The current state of the landscape is documented by the orthophotograph from 2019 (figure 11). The soil tip of Svornost is covered with wood and the grasslands are used as pastures. There are almost no remainders of the labour camp. After careful examination, it would be possible to recognize parts of fences, which, however, are not original, but they are from 2016 when some parts of the labour camp were renewed to serve as a memorial to the suffering of the political prisoners from the 1950s and 1960s (Jelen, Chromý 2018).
4.2 The region of Most

The region around Most has experienced mining for a shorter period than Jáchymov, but to a larger extent and with much more visible changes of landscape due to the type of mining. Starting in the mid-19th century, the mining of lignite (brown coal) was done underground. As the volume grew, it switched to surface mining. The expansion of mining brought rapid population growth. Between 1869 and 1910, the number of inhabitants grew more than six times in some municipalities. As a result, many new buildings appeared around the mines (Kafka 2003; Růžková, Škrabal 2006). For the comparison, the municipality of Souš (the region of Most) was chosen. The map of the Stable Cadastre (figure 12) documents the prevalence of fields (light brown), orchards and meadows (green). In relation to the underground mining, there are non-brick buildings (yellow) Sta. Maria Opferung Zech, Sta. Maria Himmelfahrt Zech and St. Antonius Zech. There is no symbol for the underground mines on the map, unlike on the map of the third military survey from 1938. The map in scale 1 : 25,000 already captures the current surface mines (Kafka 2003). Pin-gen are visible were the ground collapsed because of the mining activities underground (figure 13). The surface mining is indicated by the mine’s borders and hachures. The expanding extraction in open mines and growing soil tips in the area are even more visible in the orthophotograph from 1953 (see the Vrbenský mine and its soil tip in figure 14).

The current landscape in the region of Most is almost completely newly created – as visible in the orthophotograph from 2019 (figure 15). The memory structure of the landscape is kept only in the intangible landscape structure (e.g. the name of the extinct
village Třebušice is kept in the name of a railway stop on the way from Ústí nad Labem to Chomutov, a Jewish cemetery in Most-Souš that survived because it was, according to the convention, kept away from buildings. Alongside the surface mining of lignite, there has been restoration in progress in the areas where the mining process has finished and on soil tips. The forest and hydric restorations are used – the example is Lake Matylda in the location of the former mine Vrbenský. As the town Most is very close to the area, the restoration of soil tips is specific in regards to the social functions of the new landscape. Lakes are supposed to serve as recreation spots and there is now a racetrack on the restored soil tip of the mine Vrbenský. There are also many roads and railways that make the landscape very fragmented, gigantic industrial projects such as the power plant in Komořany and the petrochemical plant Chemopetrol in Záluží, bucket-wheel excavators, conveyor belts, abandoned mining and industrial operations and buildings. There is a net of surface energy and product conductive pipes (figure 15).

The switch in the public perception of the mining landscape in the region of Most and its history is shown in the common project of two mining companies (Vršanská uhelná and Severní energetická). The project is called Coal Safari (Uhelné safari) and the scope is to provide excursions in the functional mines and the restored areas. The participants can visit the coal mines (mines ČSA and Vršany) and to learn about technical equipment and large machinery. At the same time, the restoration is stressed as well and the landscape changes related to mining are presented (Severní energetická 2020).
4.3 The region of Kladno

Until the end of the 18th century, the landscape around Kladno had been agricultural. The maps of the Stable Cadastre show mostly fields, meadows and needleleaf forests around the village Dubí u Kladna (see figure 16). At the end of the 18th century, the first mineral deposits were discovered and the mining started to expand quickly after the beginning of the 19th century. In 1846, the main coal deposit in the region was discovered and more followed after 1850. An ironworks was founded in 1854 and it was the most important industrial project in the 19th century in the whole Bohemia (Kafka 2003). All these anthropogenic changes in the landscape are visible on the maps of the third military survey. The example in figure 17 shows the creation of the industrial zone and new mines between Kladno, Dubí and Hnidousy (the scale is 1 : 25,000). The map includes for instance smelters, ironworks and mines Praga I and Praga II. Surface mining is indicated by the mines’ borders, hachures and information about the height of the material extracted or brought.

At the end of the 19th century, some of the important deposits had been exhausted and the mining activities started to decrease. Ironworks started to be the main economic strength of Kladno. The system of mines was reduced and the industrial areas grew. In Kladno and its parts (Dubí and Hnidousy – nowadays Svermov) experienced rapid population growth. The industrial zone in Kladno is clearly visible in the orthophotograph from 1953 (figure 18). The growth and expansion of Kladno continued to the 20th century, with some slowdowns in times of crises. Reforested soil tips and the current state of the industrial zone (e.g. heating plant, railway station, former company Kablo Kladno) is easily identifiable in the orthophotograph from 2019 (figure 19).
5. Conclusion

The imprints of mining can be found in many places in Czechia. Often, there are landscape elements that are related to mining even though it is not clear at the first sight. Mining causes profound landscape changes that are identifiable dozens of years after it is over. To study the changes, it is important to provide a historical geographical approach where the study of old maps, state map series and their comparison with current sources plays a crucial role.

Each of the sample territories locations has a different history, but all of them have undergone major changes and the original landscape has been turned into a new type of landscape - post-mining landscape. Each area contains different elements and is managed in a different way. In the region of Jáchymov, the mining ended more than 50 years ago and the landscape is perceived as part of cultural heritage (which has been confirmed by the inscription in the UNESCO World Heritage List). The mining in the region was not followed by any significant restoration; the landscape around towns and villages has been basically left without interventions. Today, it is used mainly as a memorial to the mining history and its importance. The extraction of silver in the region of Jáchymov is documented already on the oldest maps (Aretin’s map, Vogt’s map, Müller’s survey of Bohemia – the symbol of crossed hammers, sometimes accompanied by the symbol of the moon). Using the cartographic symbols, the maps provide information about the location of mines and materials extracted. However, none of them provides any detail information on mining landscape elements or the extent of the mining activities. To get such information, it is better to use state map series (military surveys, Stable Cadastre) and orthophotographs from the 1950s onwards. These maps allow us to identify the whole mining area and other mining elements. It is however necessary to take into account that for example the Stable Cadastre labels the remains of mining (e.g. soil tips) as infertile soil. Therefore it is necessary to analyze these areas further and to compare them to other cartographic sources. Naturally, the same is true also for the other two locations examined. These locations have a shorter mining history compared to the region of Jáchymov and therefore it is not possible to identify mining in the oldest maps of these areas.

In contrast, the map series from the second half of the 18th century and newer provide valuable information about type, localisation and extent of mining. Each map series then has its specific characteristics. The Stable Cadastre is in a large scale and it captures the Bohemian lands in the times of agriculture intensification and at the beginning of the Industrial Revolution. Thanks to the scale, it is possible to identify the mines and mining operations. An example can be the symbol for a horse mill on the map of Jáchymov. The maps of the third military survey provide information about the period of intensive industrialization in Bohemia. This is documented for example by co-existence of the finished underground mining and the new surface mining in the region of Most. The military surveys also included both contour lines and spot heights to show the elevation and therefore it is easier to identify the changes in the terrain, such as new soil tips and surface mines.

A unique representation of the landscape is then the map series done in the 1950s by aerial photogrammetry. Thanks to these pictures it is possible to identify very accurately mining operations and other elements that do not exist anymore. Typical examples are the expansion of mining in the Most region and the labour camps in the region of Jáchymov. The reminder of the existence of the labour camps is an important aspect in the creation of cultural heritage, because it is part of history and it should not be forgotten. Thanks to the comparison of aerial photographs, it is possible to reconstruct the landscape and to remember the events that have taken place there (Hloušek 2017).

Mining is one of the most important landscape forming processes. The identification of processes and remains helps us to understand the current state of the landscape and it can also help in decision-making and in the creation of cultural heritage.
